(57) **ABSTRACT**

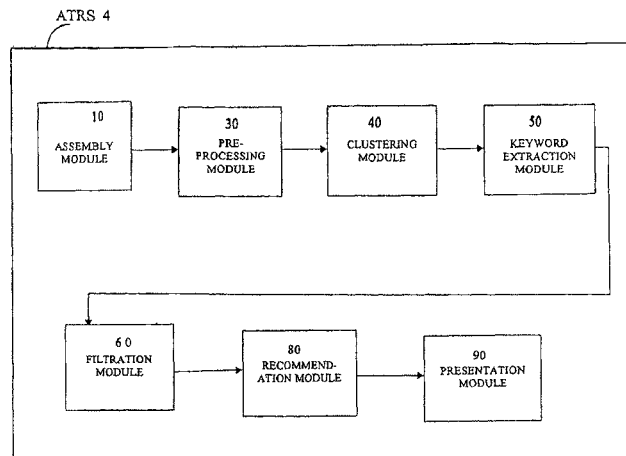

Network system provides a real-time adaptive recommendation set of documents with a high statistical measure of relevancy to the requestor device. The recommendation set is optimized based on analyzing text of documents of the interest set, categorizing these documents into clusters, extracting keywords representing the themes or concepts of documents in the clusters, and filtering a population of eligible documents accessible to the system utilizing site and or Internet-wide search engines. The system is either automatically or manually invoked and it develops and presents the recommendation set in real-time. The recommendation set may be presented as a greeting, notification, alert, HTML fragment, fax, voicemail, or automatic classification or routing of customer e-mail, personal e-mail, job postings, and offers for sale or exchange.

MESSAGE RECOMMENDATION USING WORD ISOLATION AND CLUSTERING

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation and claims the priority benefit of U.S. patent application Ser. No. 11/003,920 filed Dec. 3, 2004 and titled "System and Method for Adaptive Text Recommendation," which is a continuation and claims the priority benefit of U.S. patent application Ser. No. 09/723,855 filed Nov. 27, 2000, now U.S. Pat. No. 6,845,374 issued Jan. 18, 2005 and titled "System and Method for Adaptive Text Recommendation," the disclosure of which is incorporated herein by reference

BACKGROUND

1. Field of Invention

Invention relates to a method and system for recommending relevant items to a user of an electronic network. More particularly, the present invention relates to a means of analyzing the text of documents of interest and recommending a set of documents with a high measure of statistical relevancy.

2. Description of Related Art

Most personalization and web user analysis (also known as "clickstream") technologies work with the system making a record of select web pages that a user has viewed, typically in a web log. A web log entry records which users looked at which web pages in the site. A typical web log entry consist of two major pieces of information, namely, first, some form of user identifier such as an IP address, a cookie ID, or a session ID, and second, some form of page identifier such as a URL, file name, or product number. Additional information may be included such as the page the user came from to get to the page and the time when the user requested the page. The web log entry records are collected in a file system of a web server and analyzed using software to produce charts of page requests per day or most visited pages, etc. Such software typically relies on simple aggregations and summarizations of page requests rather than any analysis of the internal page structure and content.

Other personalization software also relies on the concept of web logs. The dominant technology is collaborative filtering, which works by observing the pages of the web site a user requests, searching for other users that have made similar requests, and suggesting pages that these other users requested. For example, if a user requests pages 1 and 2, a collaborative filtering system would find others who did the same. If the other users on the average also requested pages 3 and 4, a collaborative system would offer pages 3 and 4 as a best recommendation. Other collaborative filtering systems use statistical techniques to perform frequency analysis and more sophisticated prediction techniques using methods such as neural networks. Examples of collaborative filtering systems include NETPERCEPTIONS™, LIKE MINDS™, and WISEWIRE™. Such a system in action can be viewed at AMAZON.COM™.

Other types of collaborative filtering systems allow users to rank their interest in a group of documents. User answers are collected to develop a user profile that is compared to other user profiles. The document viewed by others with the same profile is recommended to the user. This approach may use artificial intelligence techniques such as incremental learning methods to improve the recommendations based on user feedback. Systems using this approach include SITEHELPER™, SYSKILL & EBERT™, FAB™, LIBRA™, and WEB-

WATCHER™. However collaborative filtering is ineffective to personalize documents with dynamic or unstructured content. For example, each auction in an auction web site or item offered in a swap web site is different and may have no logged history of previous users to which collaborative filtering can be applied. Collaborative filtering is also not effective for infrequently viewed documents or offerings of interest to only a few site visitors.

Clearly, there is a need for a system that considers not only the identifiers of the pages the user viewed but also the words in the pages viewed in order to make more focused recommendations to the user. Broadening the concept of pages to documents in general, there is a need for a recommendation system that analyzes the words in the document a user has expressed interest in. Such a recommendation system should support options of residing in the same computer as the web site, or on a remote server, or on an end user's computer. Furthermore, the system should be able to access documents from external sources such as from other web sites throughout the Internet or from private networks. A flexible recommendation system should also support a scalable architecture of using a proprietary text search engine or leverage off the search engines of other web sites or generalized Internet-wide search engines.

SUMMARY OF INVENTION

Invention discloses methods and systems for adaptively selecting relevant documents to present to a requester. A requestor device, either a client working on a PC, or a software program running on a server, automatically or manually invokes the adaptive text recommendation system (ATRS) and based on extracted keywords from the text of related documents, a set of relevant documents is presented to the requester. The set of recommended documents is continually updated as more documents are added to the set of related documents or interest set. ATRS adapts the choice of recommended documents based on new analysis of text contained in the interest set, categorizing the documents into clusters, extracting the keywords that capture the theme or concept of the documents in each cluster, and filtering the entire set of eligible documents in the application web site and or other web sites to compile the set of recommended documents with a high measure of statistical relevancy.

One embodiment is an application of ATRS in an e-commerce site, such as a seller of goods or services or an auction web site. A client logging onto an e-commerce site is greeted with a recommended set of relevant goods, services, or auction items by analyzing the text of the documents representing items previously bought, ordered, or bid on. As the client selects an item from the recommended set or an item on the web page, ATRS updates the documents in the interest set, categorizes the documents in the interest set into clusters, extracts keywords from the clusters, and filters the eligible set of documents at the web site to construct a recommended set. This recommended set of documents is rebuilt possibly every time the client makes a new selection or moves to a different web page.

The recommended set of documents may be presented as a panel or HTML fragment in a web page being viewed. The recommendations may be ordered for example by the statistical measure of relevancy or by popularity of the item and filtered based on information about the client.

In an alternate embodiment, ATRS may be invoked automatically by a software program to develop a recommended set for existing clients not currently logged on. The recommendations may take the form of a notification of select

clients for sales, special events, or promotions. In other alternate embodiments, the recommendations may take the form of a client alert or "push" technology data feed. Similarly, other applications of ATRS include notification of clients of upcoming television shows, entertainment, or job postings based on the analysis of the text of documents associated with these shows, entertainment or job openings in which the client has indicated previous interest.

Additional applications of ATRS include automatic classification of personal e-mail, and automatic routing of customer relations e-mail to representatives who previously successfully resolved similar types of e-mail. The recommended set may also consist of Internet bookmarks or subscriptions to publications for a "community of interest" group. Furthermore, the recommended set may be transmitted as a fax, converted to audio, video, or an alert on a pager or PDA and transmitted to the requester.

The present invention can be applied to data in general, wherein a requester device issues a request for recommended data comprising documents, audio files, video files or multimedia files and an adaptive data recommendation system would return a recommended set of such data.

BRIEF DESCRIPTION OF DRAWINGS

FIGS. 1A-1B are an architectural diagram and flow diagram, respectively, illustrating an adaptive text recommendation system invoked by a requester device, in one embodiment of the present invention.

FIG. 2 is an architectural diagram of the main components or modules of an adaptive text recommendation system in one embodiment of the present invention.

FIG. 3 is a flow diagram of the main components or modules of an adaptive text recommendation system in one embodiment of the present invention.

FIG. 4 is a flow diagram of the assembly processing of ATRS in one embodiment of the present invention.

FIG. 5 is an architectural diagram of the pre-processing of the interest set of ATRS in one embodiment of the present invention.

FIG. 6 is a flow diagram of the preprocessing of ATRS in one embodiment of the present invention.

FIG. 7 is an architectural diagram of the clustering process of ATRS in one embodiment of the present invention.

FIG. 8 is a flow diagram of the keyword extraction process of ATRS in one embodiment of the present invention.

FIG. 9 is a flow diagram of the recommendation processing of ATRS in one embodiment of the present invention.

FIG. 10A is an architectural diagram of ATRS operable in the application website whereas FIG. 10B is an architectural diagram of ATRS operable in a distributed manner with segments running at the application website and at a remote site, according to one embodiment of the present invention.

FIG. 11 is an architectural diagram illustrating the deployment of multiple applications of ATRS in and outside the United States, according to one embodiment of the present invention.

FIG. 12 is an architectural diagram of an adaptive data recommendation system in an alternative embodiment of the present invention, illustrating the data requester device invoking and receiving a set of recommended relevant data.

FIG. 13 is an architectural diagram illustrating the major input and output of an adaptive data recommendation system in an alternative embodiment of the present invention, illus-

trating the various types of data that are requested and returned to the requester device.

DETAILED DESCRIPTION

FIG. 1A shows how the requester device 2 invokes either manually or automatically a request for a set of relevant documents to ATRS 4 which processes the request and obtains a set of relevant documents from a document source 6 and returns the set to requester device 2. FIG. 1B is a high level flow diagram of ATRS consisting of steps where ATRS is invoked manually or automatically by a requester for a set of relevant documents 105 and ATRS returns a set of relevant documents 107. A requester may be a client or a software program. A requester device may be a client personal computer.

FIG. 2 shows the major modules of one embodiment of the present invention. The major modules are: Assembly Module 10, Pre-processing Module 30, Clustering Module 40, Keyword Extraction Module 50, Filtration Module 60, Recommendation Module 80, and Presentation Module 90.

The Assembly Module 10 assembles documents from multiple sources into an interest set. Documents in the interest set may include documents in a database considered of interest to the requester, web site pages previously viewed by the requester in the application web site or other web sites, documents selected by the requester from a list obtained by a search in the application web site or by an Internet-wide search, e-mail sent by the requester, documents transmitted from a remote source such as those maintained in remote servers or in other private network databases, and documents sent by fax, scanned or input into any type of computer and made available to the Assembly Module 10. For example, in an auction site, the client, presented with a list of live auction items, clicks on several auction items that are of interest, then invokes ATRS to show a set of recommended auction items.

The Pre-processing Module 30 isolates the words in the interest set and removes words that are not useful for distinguishing one document from another document. Words removed are common words in the language and non-significant words to a specific application of ATRS.

The Clustering Module 40 groups the documents whose words have a high degree of similarity into clusters.

The Keyword Extraction Module 50 determines the keyword score for each word in a cluster and selects as keywords for the cluster words with the highest keyword score and that also appear in a minimum number of documents specified for the application.

The Filtration Module 60 uses application parameters for assembling documents considered eligible for recommendation. Eligible documents may include documents from enterprise databases, documents from private network databases, documents from the application web site, and documents from public networks, such as the Internet. Furthermore, these documents may cover subjects in many fields including but not limited to finance, law, medicine, business, environment, education, science, and venture capital. Application parameters may include age of documents and or client data that specify inclusion or exclusion of certain documents.

The Recommendation Module 80 calculates the relevance score for eligible documents to a cluster and ranks the eligible documents by relevance score and other application criteria. Top scoring documents are further filtered by criteria specific to the client.

The Presentation Module 90 personalizes the presentation format of the recommendations for the client. Examples of formats are e-mail, greetings to a site visitor, HTML fragment

5

or a list of Internet sites. Any special sorting or additional filtration for the client is applied. The recommendations are converted to the desired medium, such as voicemail, fax hardcopy, file transfer transmission, or audio/video alert.

FIG. 3 is a flow chart of one embodiment of the present invention starting with the assembly of documents from multiple sources into an interest set **110**; pre-processing of the documents to remove “stop” words **112**; grouping the documents in the interest set into clusters **114**; extraction of keywords contained in documents included in the clusters **116**; filtration of documents eligible to be considered for recommendation for each cluster **118**; construction of a recommendation set of documents per cluster **120**; and presentation of the recommendations **122**.

FIG. 4 is a flow chart of the Assembly Module **10** illustrating the process involved in assembling all documents which comprise the interest set. Documents previously recorded for the client **130** may include previous purchases in a e-commerce site, bids in an auction site, or web pages visited by client which contain tags that automatically trigger communication to a server of the page or data involved. Documents may include those corresponding to the navigation path of the client in the website **132**. The client may have selected documents from a list of web pages **134** as a result of a site search or an Internet-wide search. Other documents may include e-mails, faxed document, scanned documents or any other form of document input associated with the client **136**. Alternatively, documents included may be those transmitted through a network for the client **138** where the storage of documents is done remotely. All input documents are assembled into an interest set **140**.

FIG. 5 is an architectural chart illustrating the use of the assembled interest set **26** and the Stop Word Database **32** in the Pre-processing Module **30** to create the refined interest set of documents **34**. The Stop Word Database **32** comprises words that are not useful for distinguishing one document from another document in the interest set. If the application language is English, examples would include words such as ‘and’, ‘the’, and ‘etc.’ The Stop Word Database **32** also includes words that are common in the interest set as a result of the purpose, application or business conducted for the site. For example, on an auction site, each web page containing an item description might also contain the notice “Pay with your Visa card!” In this case, the words ‘pay’, ‘visa’, and ‘card’ would be included in the Stop Word Database **32**.

FIG. 6 is a flow chart illustrating the process performed in the Pre-processing Module **30** in one embodiment. The process includes isolating words in the documents of the interest set and converting the words into a common format **150**, such as converting the words to lower case. A word is an alphanumeric string surrounded by white space or punctuation marks. Next, if a word is a common word of the language **152** the word is removed **158**. If a word is a non-significant word specific to the site and the application **154**, it is also removed **158**. Otherwise, the word is retained in the document **156**. In one embodiment, the common words of the language and the non-significant words specific to the application are maintained in the Stop Word Database **32**.

FIG. 7 is an architectural chart illustrating the use of the refined interest set **34** and processing in the Clustering Module **40** to group the documents into clusters **42**, **44**, and **46**. Clustering is the process of grouping together documents in the interest set whose words have a high degree of similarity. In one embodiment of the present invention, the similarity of two documents D.sub.1 and D.sub.2 is denoted by similarity (D.sub.1, D.sub.2). If D.sub.1 does not contain any words in common with D.sub.2, then:

6

similarity(D₁, D₂)=0.

If the two documents have words in common, then:

$$\text{similarity}(D_1, D_2) = \frac{\sum_{w \in D_1 \cap D_2} \text{count}(w, D_1) \text{count}(w, D_2)}{\left[\sum_{w \in D_1 \cap D_2} \text{count}(w, D_1)^2 \right]^{1/2} \left[\sum_{w \in D_1 \cap D_2} \text{count}(w, D_2)^2 \right]^{1/2}},$$

where count (w, D) denotes the number of occurrences of the word w in the document D, and $w \in D_1 \cap D_2$ denotes a word that appears in both D₁ and D₂. Many other definitions of similarity between two documents are possible.

The clustering criteria may vary depending on the application of ATRS **4**. An advantageous implementation involves arranging the documents from the interest set so as to maximize the cluster score, wherein the cluster score of a cluster containing only one document is zero and the cluster score for a cluster containing more than one document is the average similarity score between the documents in the cluster.

The clustering algorithm can be any one of well-known clustering algorithms that can be applied to maximize the clustering criterion, such as K-Means, Single-Pass, or Buckshot, which are incorporated by reference.

FIG. 8 is a flow diagram of the keyword extraction processing of ATRS **4** in one embodiment of the present invention. For each word w in a cluster C, calculate the frequency of the word w in the interest set, Frequency(w); and calculate the frequency of the word w in cluster C, Frequency(w, C) **180**. Calculate the keyword score for word w in the cluster C **182**, using the equation:

$$\text{Keyword score } (w, C) = \log \text{Frequency } (w, C) - \log \text{Frequency } (w)$$

Select keywords for cluster C based on application criteria **184**; for example, select keywords that have high scores and appear in several documents. Upon processing all clusters **186**, the system proceeds to the balance of processing. In an alternative embodiment of the present invention, the keywords describing the theme or concept in a cluster do not necessarily appear in the text of any document, but instead summarize the theme or concept determined, for example, by a method for natural language understanding.

FIG. 9 is a flow diagram of the recommendation processing of ATRS **4** in one embodiment of the present invention. For each eligible document D, count the number of times the keyword w.di-elect cons.keywords(C) appears **190**. Calculate the relevance score of document D to cluster C using the equation:

$$\text{relevance}(D, C) = \frac{\sum_{w \in \text{keywords}(C)} \text{count}(w, D)}{\left[\sum_{w \in \text{keywords}(C)} \text{count}(w, D)^2 \right]^{1/2}},$$

where $w \in \text{keywords}(C)$ denotes one of the keywords of cluster C.

Rank eligible documents by relevance score and other application criteria **194**. Retain top scoring documents and apply other filtration criteria specific to this client **196**. For example, the client may only want documents created within the last seven days. At the completion of all clusters **198**, the system proceeds to the balance of processing.

The presentation of recommendations may be through a set ordered by relevance score, set ordered by popularity of document, a greeting to a site visitor, a notification of a sale, event, or promotion, a client alert, for example, a sound indicating presence of a new document, or a new article obtained from a newswire as in "push" data feed delivery methods, notification of TV shows and entertainment based on processing the descriptions of previously viewed TV programs or purchased tickets for entertainment shows. Hard copy formats in the form of postcards, letters, or fliers may also be the medium of presentation.

Another embodiment of the present invention is conversion of the recommendation set of documents into files for faxing to the client, conversion to voice and presenting it as a voice-mail, a pager or audio or video alert for the client. Advantageously, such recommendations can be sent through a network and stored for later retrieval. In another embodiment, the system may serve a "community of interest" like a wine connoisseur's Internet list or chat room where the recommendation may consist of the popular magazines or web pages viewed by experts of the community of interest. Alternatively, the recommendation may be presented to the client or requester as a set of Internet bookmarks.

There are several alternative embodiments of the present invention. In a document classification application, customer e-mails sent to a company's customer service representative (CSR) department can be routed to the CSR that had successfully resolved similar e-mails containing the same issues. A similar application is the automatic classification of personal e-mail wherein ATRS processes e-mails read and or responded to by the client, applying the clustering/keyword extraction/filtering/recommending steps to present the recommended e-mails to the client, treating the rest as miscellaneous. The client may further specify presentation of the top ten e-mails only, a very useful feature for e-mail access on wireless devices. Other classification applications are automatic routing of job postings to a job category, and automatic classification of classified advertisements or offers for sale or offers to swap items or services.

Other applications of ATRS involve research either in the Internet or in enterprise databases. For example, a client may be interested in "banking". Instead of sifting through multitudes of documents that contains "banking", the client may "mark" several documents and invoke ATRS to present a set of recommended documents with a high measure of statistical relevance. This research may be invoked on a periodic basis wherein ATRS presents the recommended set of documents to the client in the form of a notification or to clients in the "community of interest" application.

In another application of ATRS, online auction participants who have lost an auction are sent e-mail or other notification containing a list of auctions that are similar to the one they lost. This list is generated based on textual analysis of the description of the lost auction.

Another application of ATRS involves analyzing the text of news stories or other content being viewed by a site visitor and displaying a list of products whose descriptions contain similar themes or concepts. For example, a visitor to a web site featuring stories about pop stars might read an article about Madonna and be presented a list of Madonna-related products such as musical recordings, clothing, etc. The presentation of the recommended products might be done immediately as the site visitor is browsing, or upon returning to the web site, or in an e-mail, or other delayed form of notification.

Similarly, ATRS can work in conjunction with a regular search engine to narrow the results to a more precise recommended set of documents. In one embodiment, ATRS 4 is a

front-end system of a network search engine. ATRS 4 analyzes the text of an interest set of documents, groups the interest set of documents into clusters; extracts keywords from the text of the documents grouped into the clusters; and communicates the selected keywords of the clusters to the search engine. The search engine uses these keywords to search the network for documents that matches the keywords and other filtering criteria that may be set up for the application.

FIG. 10A is an architectural diagrams where the requester device 2 may be a PC used by a client to access a website and ATRS 4 is manually or automatically invoked upon accessing the site. The document source 6 may be at the website or may be the entire Internet. FIG. 10B shows an alternative embodiment of the present invention wherein the requestor device 2 is essentially unchanged but the application website 300 for ATRS 4 only hosts the ATRS shell 300 or application proxy and the ATRS modules 305 are operable in a remote site. Document source 6 may be operable in a distributed manner at the same or different remote site as the ATRS modules 305. Alternatively, document source 6 may be the entire Internet.

FIG. 11 is an architectural diagram illustrating the deployment of multiple applications of ATRS 4 in and outside the United States, according to the present invention. Requestor device 1310, is in the United States, and Requestor device 2312, is located outside of the United States. Requestor device 1310 and Requestor device 2312, are coupled to ATRS 1314 in the United States and or ATRS 2316 located outside of the United States. Document Source 1318 is in the United States whereas Document Source 2320 is outside the United States and both are coupled to and provide eligible documents for ATRS 1314 and or ATRS 2316.

FIG. 12 is an architectural diagram of an adaptive data recommendation system in an alternative embodiment of the present invention, illustrating the data requester device 330 invoking and receiving a set of recommended relevant data from an adaptive data recommendation system 332 using data source 334.

FIG. 13 is an architectural diagram illustrating the major input and output of an adaptive data recommendation system in an alternative embodiment of the present invention, illustrating the various types of data that are requested and returned to the requestor device. A document interest set 340, audio interest set 342, a video interest set 344, and or a multimedia interest set 346 are accessed by an adaptive data recommendation system 332, utilizing a data source 334, a client database 348, and application parameters 358 to create a recommended data set comprising document recommended set 350, audio recommended set 352, video recommended set 354, and multimedia recommended set 356. As an example, based on the description of various artists and their singing styles, a requester device may specify certain singers with the type of songs and lyrics desired, an adaptive data recommendation system would cluster the songs and artists, extract keywords of the lyrics or key notes or note patterns in the artists' songs, and search sites containing libraries of artists and songs, and select for recommendation the downloadable songs relevant to requestor's criteria. The recommendation could be streaming audio or streaming video that can be played at the requester device.

One implementation of the present invention is on a Linux OS running Apache web server with a MySQL database. However, a person knowledgeable in the art will readily recognize that the present invention can be implemented in different operating systems, different web servers with other types of data bases but not limited to Oracle and Informix.

A person knowledgeable in the art will readily recognize that the present invention can be implemented in a portable device comprising a controller; memory; storage; input accessories such as a keyboard, pressure-sensitive pad, or voice recognition equipment; a display for presenting the recommended set; and communications equipment to wirelessly-connect the portable device to an information network. In one embodiment, the ATRS computer readable code can be loaded into the portable device by disk, tape, or a hardware plug-in, or downloaded from a site. In another embodiment, the logic and principles of the present invention can be designed and implemented in the circuitry of the portable device.

Foregoing described embodiments of the invention are provided as illustrations and descriptions. They are not intended to limit the invention to precise form described. In particular, it is contemplated that functional implementation of the invention described herein may be implemented equivalently in hardware, software, firmware, and/or other available functional components or building blocks.

Other variations and embodiments are possible in light of above teachings, and it is thus intended that the scope of invention not be limited by this Detailed Description, but rather by claims following.

What is claimed is:

1. A method for recommending electronic-mail messages, the method comprising:

assembling electronic-mail messages into an interest set, the electronic-mail messages having been previously viewed and responded to by a user, wherein the electronic-mail messages are assembled into an interest set by an assembly module stored in memory, the assembly module executed by a processor;

isolating words in the interest set, wherein the words are isolated by a pre-processing module stored in memory, the pre-processing module executed by a processor;

grouping electronic-mail messages in the interest set into clusters of electronic-mail messages having a level of similarity amongst the isolated words, wherein the electronic-mail messages are grouped by a clustering module stored in memory, the clustering module executed by a processor;

generating a keyword for each cluster, the keyword identified based on one or more terms identified via natural language understanding and representing the theme of the electronic-mail messages in each cluster, wherein the keyword is not one of the terms identified via natural language understanding, the keywords generated by a keyword module when executed by a processor;

recommending an electronic-mail message received subsequent to the generation of the keywords for further action based upon a ranking of the subsequently received electronic-mail message, the ranking based on a number of times one of the generated keywords of the clusters appears in the subsequently received electronic-mail message, wherein the electronic-mail message is recommended by a recommendation module stored in memory, the recommendation module executed by a processor; and

adding the recommended electronic-mail message to the interest set when the user responds to the recommended electronic-mail message by taking the further action, wherein the electronic-mail message is added by the assembly module.

2. The method of claim 1, wherein the electronic-mail messages are from multiple sources.

3. The method of claim 1, wherein execution of the pre-processing module by the processor results in removal of words that are not useful for distinguishing one electronic-mail message from another.

4. The method of claim 3, wherein the non-useful words removed by execution of the pre-processing module are words common to the language of the electronic-mail message.

5. The method of claim 3, wherein the non-useful words removed by execution of the pre-processing module are words that are insignificant to the recommendation.

6. The method of claim 1, further comprising filtering each cluster based on a client-defined limit on electronic-mail message age and an age associated with each electronic-mail message in each cluster, wherein the electronic-mail messages are filtered by a filtration module, the filtration module executed by a processor.

7. A non-transitory computer-readable storage medium having embodied thereon a program, the program being executable by a processor to perform a method for recommending a message, the method comprising:

assembling electronic-mail messages into an interest set, the electronic-mail messages having been previously viewed and responded to by a user;

isolating words in the interest set;

grouping electronic-mail messages in the interest set into clusters of electronic mail messages having a level of similarity amongst the isolated words;

generating a keyword for each cluster, the keyword identified based on one or more terms identified via natural language understanding and representing the theme of the electronic-mail messages in each cluster, wherein the keyword is not one of the terms identified via natural language understanding;

recommending an electronic-mail message received subsequent to the generation of the keywords for further action based upon a ranking of the subsequently received electronic-mail message, the ranking based on a number of times one of the generated keywords of the clusters appears in the subsequently received electronic-mail message; and

adding the recommended electronic-mail message to the interest set when the user responds to the recommended electronic-mail message by taking the further action.

8. The non-transitory computer-readable storage medium of claim 7, wherein words that are not useful for distinguishing one electronic-mail message from another are removed.

9. The non-transitory computer-readable storage medium of claim 8, wherein the removed non-useful words are words common to the language of the electronic-mail message.

10. The non-transitory computer-readable storage medium of claim 8, wherein the removed non-useful words removed are words that are insignificant to the recommendation.

11. The non-transitory computer-readable storage medium of claim 7, wherein the method further comprises filtering each cluster based on a client-defined limit on electronic-mail message age and an age associated with each electronic-mail message in each cluster.

12. A network device, comprising:

a network interface for receiving electronic-mail messages over a communications network;

a processor; and

memory storing:

an assembly module that is executable by the processor and assembles electronic-mail messages into an interest set, the electronic-mail messages having been previously viewed and responded to by a user,

11

a pre-processing module that is executable by the processor and isolates words in the interest set,
a clustering module that is executable by the processor and groups electronic-mail messages in the interest set into clusters of electronic-mail messages having a level of similarity amongst the isolated words, 5
a keyword module that is executable by the processor and generates a keyword for each cluster, the keyword identified based on one or more terms identified via natural language understanding and representing the theme of the electronic-mail messages in each cluster, wherein the keyword is not one of the terms identified via natural language understanding, and 10
a recommendation module that is executable by the processor and recommends an electronic-mail message received subsequent to the generation of the keywords for further action based upon a ranking of the subsequently received electronic-mail message, the ranking based on a number of times one of the generated keywords of the clusters appears in the subsequently received electronic-mail message, wherein the recommended electronic-mail message is added to the interest set when the user responds to the recommended electronic-mail message by taking the further action. 25

13. The network device of claim **12**, wherein the memory further stores a filtration module that is executable by the processor and filters each cluster based on a client-defined limit on electronic-mail message age and an age associated with each electronic-mail message in each cluster. 30
